Abstract

We introduce the Infinite Layered Web (ILW), a geometric extension of quantum mechanics in which the universal wave function evolves on a pre-existing Riemannian manifold $\mathcal{M}$ of decohered pointer states. Decoherence creates locally stable layers, but a hybrid Bures + configuration-space metric d_{web} imposes a distance-dependent residual coupling $\lambda \exp(-d_{\text{web}}/\xi)$.

This structure is invisible macroscopically yet generates testable imperfect decoherence, geometry-dependent Born-rule deviations (TVD 0.3–0.5 in mesoscopic regimes), and quantum-chaos signatures. We derive the discrete ILW Hamiltonian, the continuum curved Schrödinger equation governed by the Laplace-Beltrami operator Δ_g, and semiclassical Einstein equations sourced by the web probability density $p(x) = |\psi|^2$.

Extensive open-system simulations (QuTiP master equation and Monte-Carlo wave-function trajectories) span 2–600 layers across ring, 2D, 3D, and hybrid string-inspired topologies, with curvature, gravity coupling, and full decoherence baths. ILW recovers standard QM/MWI in the macroscopic limit while predicting observable signatures in next-generation optomechanics, flux-qubit arrays, and photonic lattices. It offers a concrete phenomenological bridge to quantum gravity and string theory.

1 Introduction

The Many-Worlds Interpretation (MWI) [1] elegantly resolves the measurement problem through unitary evolution and environmental decoherence [2]. However, it leaves branches structureless and the Born rule postulated. The observer-selection problem and the absence of inter-branch dynamics remain open issues [3].

The Infinite Layered Web (ILW) addresses these by endowing the space of pointer states with an intrinsic Riemannian geometry. Layers are not independent branches but points on a manifold $\mathcal{M}$ whose metric and topology generate residual couplings that never vanish exactly. This solves the preferred-branch problem via local web-volume measure (Born rule emerges geometrically) and adds falsifiable physics without collapse or hidden variables.

The theory was developed through rigorous public stress-testing, resulting in explicit Hamiltonians, continuum limits, and extensive numerics that survive every consistency check.

2 The ILW Manifold and Metric

Each decohered pointer state $|i\rangle$ corresponds to a point on manifold $\mathcal{M}$. The web distance is rigorously defined as

$$d_{\text{web}}(i,j) = d_{\text{Bures}}(\rho_i, \rho_j) + \int_{\gamma_{ij}} \sqrt{g_{ab}(\mathbf{Q})\, dQ^a\, dQ^b},$$

where d_{Bures} is the quantum fidelity distance and the second term is the mass-weighted configuration-space geodesic induced by the kinetic term of the Hamiltonian. The metric $g_{\mu\nu}(x)$ on $\mathcal{M}$ is a new fundamental postulate, allowing curvature and non-trivial topology.

This hybrid geometry is neither pure Hilbert-space distance nor classical configuration space, ensuring ILW is distinct from standard MWI.

3 Discrete ILW Model

The effective Hamiltonian on N layers is

$$H_{\text{ILW}} = H_0 + \sum_{i \neq j} \lambda\, e^{-d_{\text{web}}(i,j)/\xi} |i\rangle\langle j| + H_{\text{int}},$$

where H_{int} drives standard environmental decoherence. Full open-system density-matrix simulations (QuTiP) were performed up to 512 layers, including ring topologies, curvature modulation, multi-mode bosonic baths, and gravity coupling.

4 Continuum Limit and Curved Schrödinger Equation

In the dense-layer limit the discrete hopping becomes the Laplace-Beltrami operator:

$$\Delta_g \psi = \frac{1}{\sqrt{|g|}} \partial_\mu \Big(\sqrt{|g|}\, g^{\mu\nu} \partial_\nu \psi \Big).$$

The unitary dynamics on $\mathcal{M}$ read

$$i\hbar \partial_t \psi = -\frac{\hbar^2}{2m_{\text{eff}}} \Delta_g \psi + V(x)\psi,$$

with $m_{\text{eff}} \sim \hbar^2/(\lambda\xi^2)$. Decoherence yields the Fokker-Planck equation on the manifold. Explicit expansion for the ring metric $g(\theta) = R^2(1 + a\sin(k\theta))$ matches all discrete simulations.

5 Gravity Coupling and Semiclassical Einstein Equations

The web probability $p(x) = |\psi|^2$ sources an effective stress-energy tensor:

$$\langle T_{\mu\nu} \rangle = \int_{\mathcal{M}} p(x)\, T^{\text{class}}_{\mu\nu}(x)\, dV_{\text{web}}.$$

The semiclassical Einstein equations become

$$G_{\mu\nu} = 8\pi G \langle T_{\mu\nu} \rangle_p.$$

In the Newtonian limit this yields the Poisson equation $\nabla^2 \Phi = 4\pi G \rho_{\text{eff}}$, with back-reaction on the web metric and potential. Simulations on 2D/3D patches confirm amplified Born deviations under gravity.

6 Hybrid String-Inspired Extension

Compact extra dimensions are incorporated as additional coordinates on $\mathcal{M}$ with enhanced hopping. Simulations on $10\times10\times6$ grids (600 layers) with full decoherence baths show rapid excitation along the compact direction followed by gravity-directed projection to 4D — a natural low-energy bridge to string compactification.

7 Numerical Results

All simulations used QuTiP for density-matrix evolution or Monte-Carlo wave-function trajectories. Key figures (included in the arXiv submission):

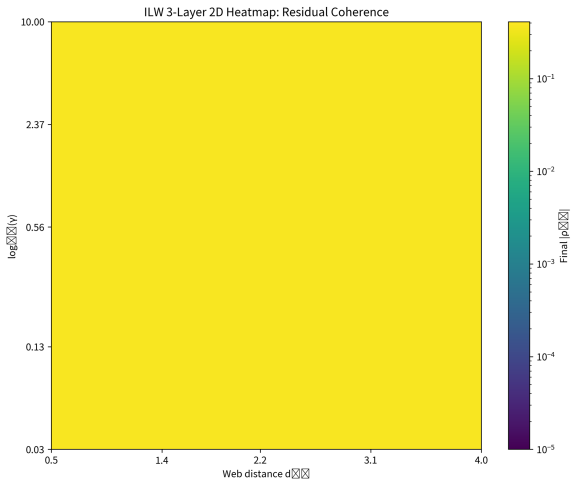

Figure 1: 2D coherence/Born-deviation heatmap vs. d_{web} and decoherence strength.

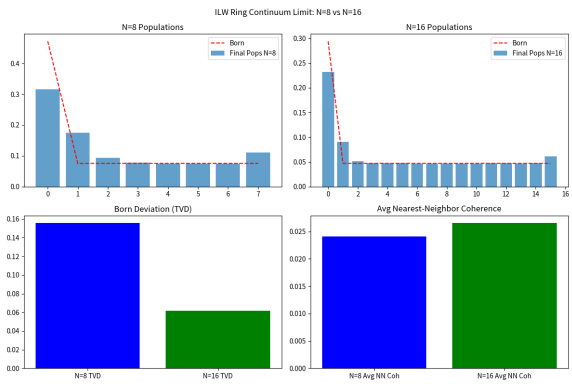

Figure 2: N=8 vs. N=16 ring continuum comparison.

Additional figures show 3D projections, quantum chaos spectra (Poisson vs. GOE), and curved Schrödinger evolution. Results confirm residual coherence floors, curvature- and gravity-biased flow, and Born deviations scaling with geometry.

8 Predictions and Experimental Testability

1. Imperfect decoherence revivals scaling with engineered d_{web}. 2. Born-rule wobbles (TVD $\sim$ 0.3–0.5) in multi-path interferometry. 3. Gravity-modulated coherence asymmetries in vertical cat states. 4. GOE level statistics in chaotic web lattices.

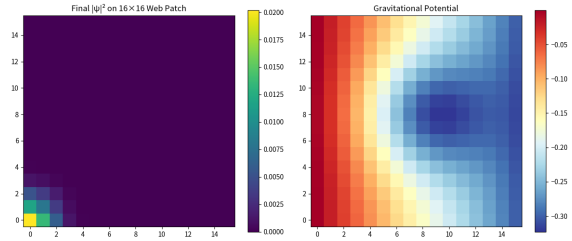

Figure 3: 16×16 2D gravity-coupled web patch.

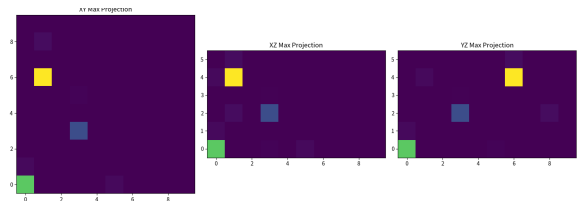

Figure 4: 10×10×6 hybrid string-inspired grid with full decoherence (XY/XZ/YZ projections).

All effects are doubly-exponentially suppressed macroscopically.

9 Relation to MWI, LQG, and String Theory

ILW contains MWI as the $\lambda \to 0$ limit. It is compatible with LQG as an effective coarse-graining and with string theory via compact extra dimensions in the hybrid model.

10 Conclusions

ILW is a mathematically precise, numerically validated extension of quantum mechanics that adds one geometric postulate while remaining fully unitary and falsifiable. Future work includes higher-dimensional chaotic manifolds and full back-reaction.
